Results for EU

Results for Coal-6

Results on country level

Methodology & main assumptions

Strategic reserves

EXECUTIVE SUMMARY

Methodology & scenarios

SCENARIO DESIGN

- Definition of political scenarios
- Basis for power market modeling

ASSUMPTIONS

- Techno-economical parameters
- RES, coal trajectories
- CO₂ prices

MODELING

- Power plant dispatch & investment up to 2030
- Development of capacity and generation mix

RESULTS

- Incremental generation costs* (ICG)
- Investment volumes
- CO₂- and other emissions

MODELING APPROACH

EU-27 countries** aggregated and major coal-countries as focus group („Coal-6“): BG, CZ, DE, PL, RO, SI

REGIONAL SCOPE

40 % reduction scenario

40 % Policy mix
(40 % PM)

Policy mix – “40 % Scenario” implies the former EU 2030 carbon mitigation ambition level. No significant market based coal exit or RES expansion. CO₂ price based on EC Reference 2016 sc. (35 €/t in 2030).

55 % reduction scenarios

55 % Policy mix
(55 % PM)

Policy mix - complete coal exit until end of 2030 and increased, policy-driven RES expansion as well as elevated CO₂ prices (54 €/t in 2030 based on TYNDP2020).

55 % Market based coal exit
(55 % MCE)

Market based coal exit - coal exit trajectory resulting from relying on an economic decommissioning of all coal plants driven by the CO₂ price. RES expansion remains policy-driven.

55 % market based coal-to-clean
(55 % MCTC)

Market based coal exit and RES expansion - further explores the requirements and implications of a CO₂ price-driven coal-to-clean transformation.

SCENARIOS

* For an economic comparison of scenarios the differences in generation cost are of main relevance. This study looks at an indicator called “Incremental generation costs”. For a detailed explanation see methodology section. ** excl. island markets of Malta, Cyprus.

CO₂ price* trajectories

40 % and 55 % PM scenario trajectories based on projections in reference sources (EC2016 Ref / TYNDP DE sc.). 55 % MCE & 55 % MCTC trajectories result from heuristically iterations as described in the methodology section.

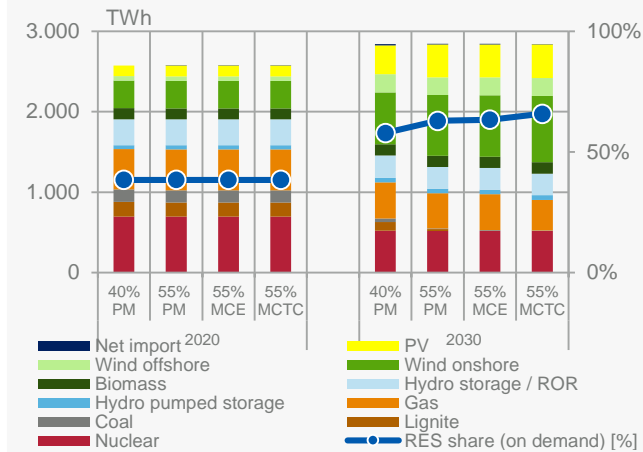

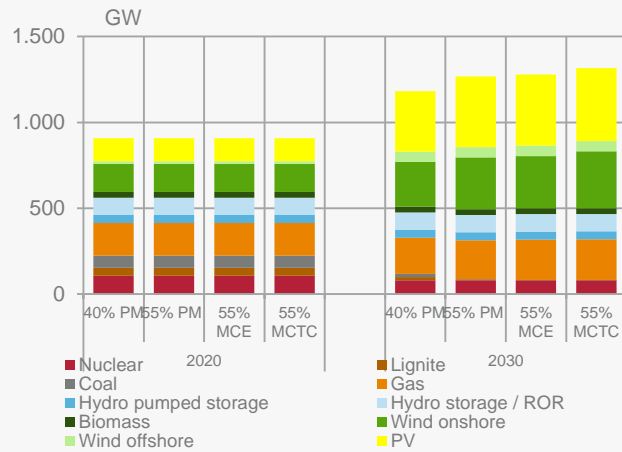

* real 2021 prices

Key results – EU

Capacities

- Phase out of remaining 38 GW of coal capacities in 55 % scenarios
- Substitution with 100 GW mix of wind onshore, PV & minor flexible gas capacity

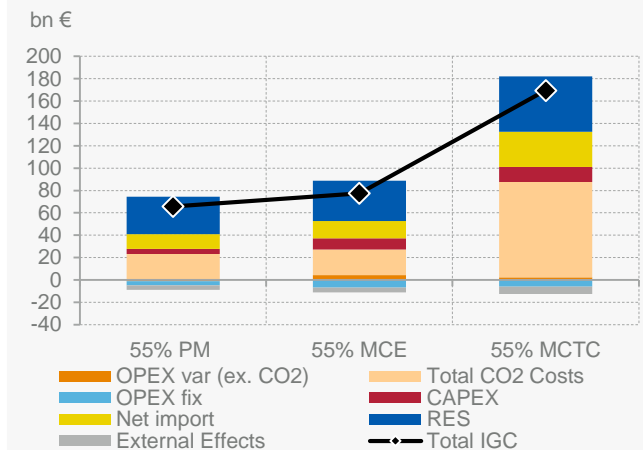

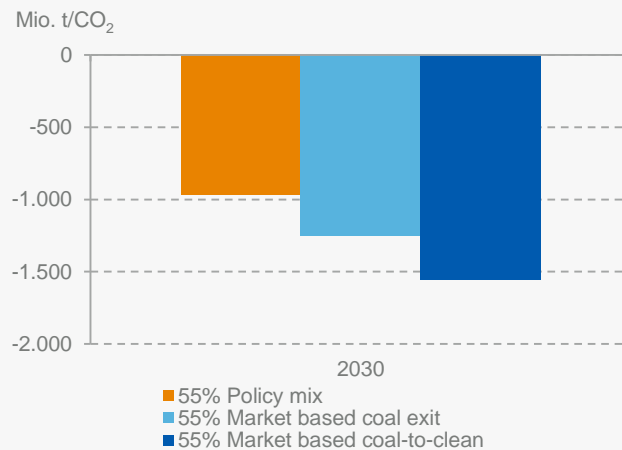

Generation

- Less carbon-intensive EU generation mix in the 55 % scenarios
- RES shares increase by over 5 percentage points compared to 40 % PM

Total CO₂ emission deltas

- Significant CO₂ savings in 55 % scenarios over the decade
- Incremental effects of higher EU ETS prices are limited by reduced coal-capacity over time

Total IGC deltas

- IGC in a similar range in the 55 % PM and 55 % MCE scenarios
- Much higher CO₂ price in 55 % MCTC drives IGC up. However, related costs do create additional public income

Conclusions

A clear pathway to „-55 % in 2030“

A coal exit until 2030 is feasible

A strong ETS price leads the way

Market-driven coal exit on the doorstep

Renewable support likely to remain until 2030

The trajectory to reach the 2030 target is clear: A phase-out of the remaining 38 GW (in 2030) coal capacities in the EU countries in 2030 is met with 100 GW additional wind and PV. Additional costs to the consumer versus the baseline remain limited in the range of 3-7 €/MWh with an average of 5 €/MWh.

Modelling indicates that a full coal exit until 2030 is possible with additional market based deployment of gas of around 15 GW and overall investment volumes of 82 bn €. Additional reserves would be necessary to cover national peak loads nationally or secure non-standard weather years. This would imply building on average two additional gas-based power plants per year in between 2024 and 2030 in the EU, which seems feasible but given the timeline would need a fast decision on governance and incentive structures.

Three core policy approaches are available to incentivize necessary developments: increased ETS-carbon pricing, national policies to govern coal phase-outs and support of renewable expansion. The higher the European ambition in regards to ETS pricing, the fewer national policies are necessary to reach the target. The currently assumed ambition to increase the reduction target and reform the ETS* already significantly reduces the need for additional national incentives, but not completely.

The modelling indicates that sustained prices above 65 €/t alongside the necessary RE expansion could lead to a full and market-driven coal phase-out. Any national regulation on coal phase-out should therefore take care not overcompensate plant closures to even slow down this development.

With increasing renewable penetration, the ability to integrate additional renewable volumes decreases. Therefore, to fully phase out support mechanisms for renewables a much higher CO₂ price, in the range of up to 150 €/t, would be necessary. This would lead to major distributional challenges (increasing power prices vs. increasing revenues from CO₂ auctions), which would be difficult to resolve.

* Projections ranging from ~54 €/t (entso-e TYNDP2020 Distributed Energy Scenario) to ~70-80 €/t (EC ETS amendment proposal annex, COM(2021) 551 final) in 2030.

RESULTS FOR EU

Total emissions & system costs – EU

All coal-exit scenarios result in significant reduction of CO₂. Incremental effects of higher CO₂ prices are diminishing as coal capacity is decreasing. Additional IGC are in a similar range in the 55 % PM and 55 % MCE scenarios, while higher CO₂ price in 55 % MCTC drives IGC up significantly at EU level as it affects markets without potential for coal substitution.

Capacity & generation - EU

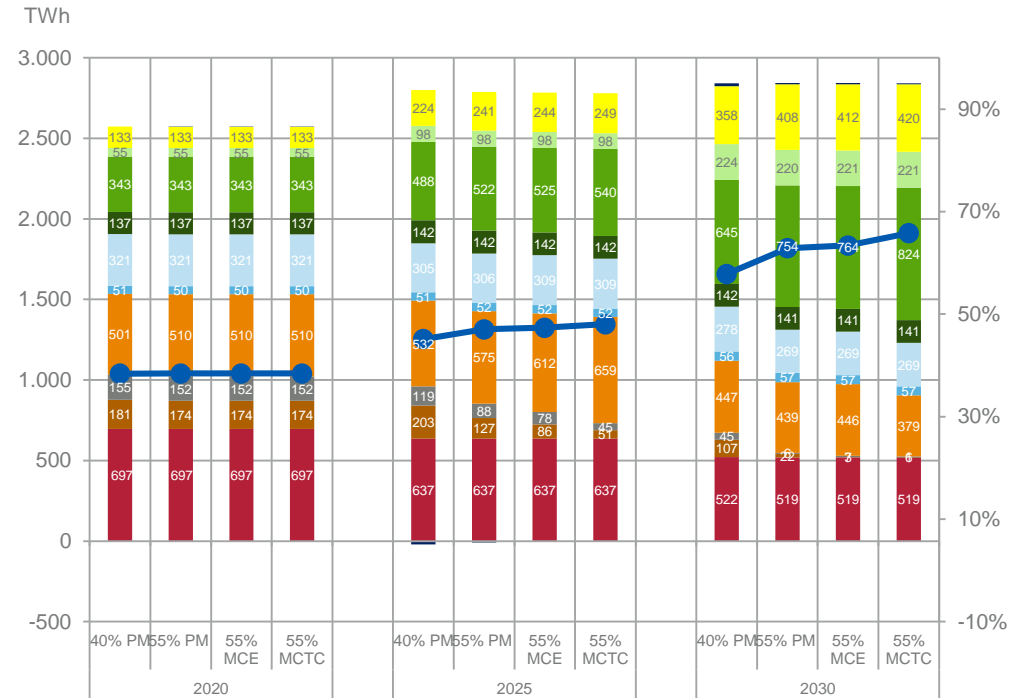

Compared to the 40 % PM scenario, the 55 % scenarios see an accelerated reduction of remaining coal capacities, which are substituted with a mix of wind onshore, PV & gas units (flexibility demand). The EU generation mix becomes less carbon-intensive in the 55 % scenarios and RES shares increase by over 5 percentage points by 2030, and more in MCTC due to additional market based expansion.

PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Scenario differences: Installed capacities at EU level

In all 55 % scenarios, the remaining coal capacities are substituted with a mix of wind onshore, PV and gas. Compared to the 55 % PM, the 55 % Market based scenarios see an earlier and steeper capacity reduction of coal units driven by higher CO₂ price trajectories. Higher CO₂ prices also trigger additional market based RES expansion, especially in the 55 % Market based coal-to-clean scenario.

Scenario differences: Power generation at EU level

Earlier decommissioning and lower utilization of the remaining coal-fired units trigger temporary increased gas-based generation (mid-term), especially in both 55 % Market based scenarios. In the long run, coal-based generation is compensated by PV, wind onshore and some gas-based generation. All scenarios lead to an increase in renewable energy generation of over 150 TWh by 2030.

Note: Graphs depict scenario differences to the 40% PM scenario (e.g. 55 % PM minus 40 % PM). PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Scenario differences: CO₂ emissions at EU level

All 55 % scenarios lead to significant CO₂ savings compared to the 40 % PM scenario. Until 2024, the additional reduction is driven only by the CO₂ price. In total, the 55 % PM results in CO₂ reduction of 964 Mio. t by 2030, the 55 % MCE by an additional 282 Mio. t of this reduction. In the 55 % MCTC scenario a larger (compared to 55% PM) reduction 594 Mio. t CO₂.

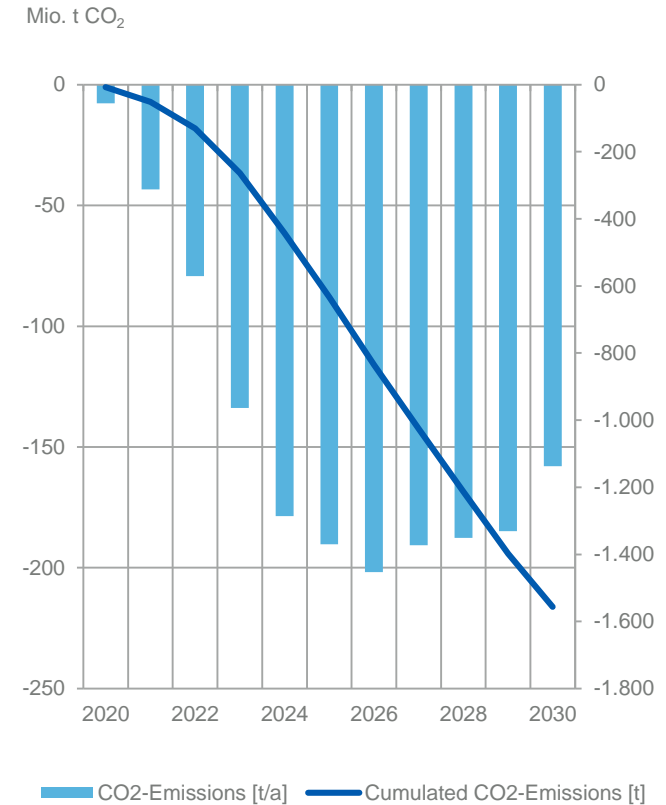

55 % PM

55 % MCE

55 % MCTC

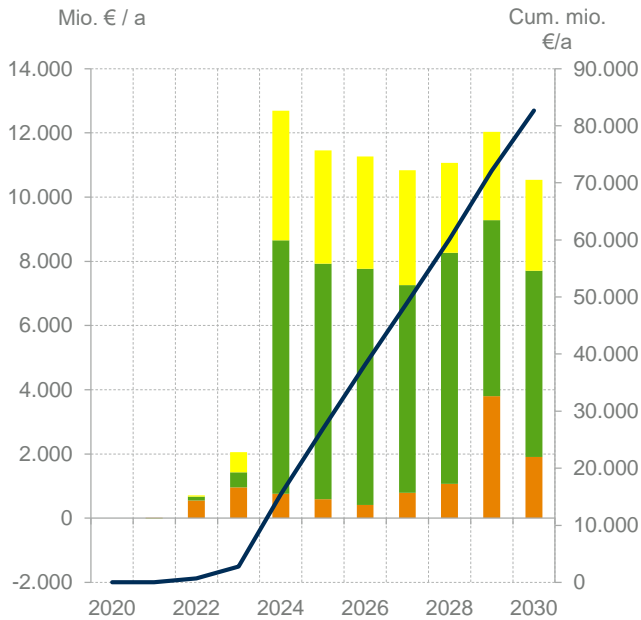

Note: Graphs depict scenario differences to the 40% PM scenario (e.g. 55 % PM minus 40 % PM). PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Scenario differences: Investment volumes at EU level

Required additional investments into the power-generating infrastructure of the EU accumulate to 83 bn € (55 % PM), 96 bn € (55 % Market based coal exit) and 131 bn € (55 % Market based coal-to-clean) until 2030. Additional investments are mainly channelled towards onshore wind and PV assets and, to a lesser extent, into gas-based capacities.

55 % PM

55 % MCE

55 % MCTC

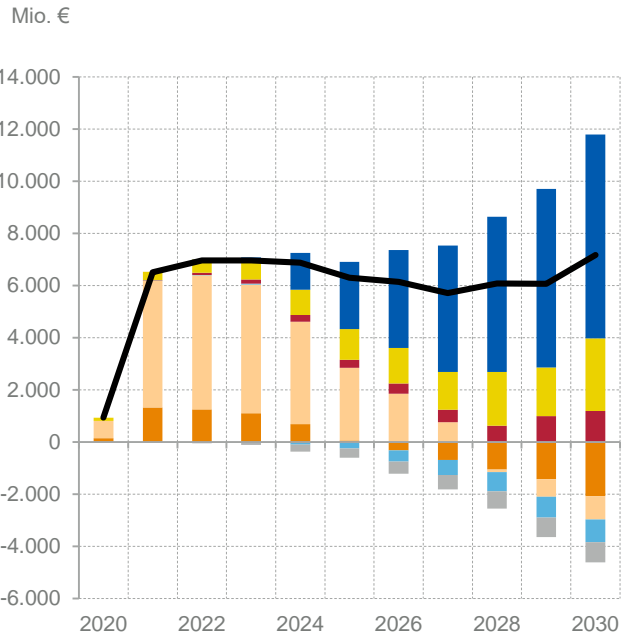

Note: Graphs depict scenario differences to the 40% PM scenario (e.g. 55 % PM minus 40 % PM). PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

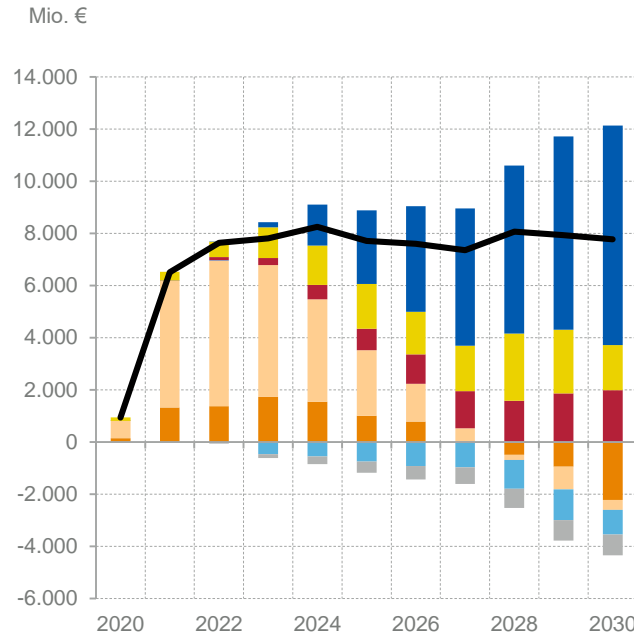

Scenario differences: Incremental generation costs at EU level

Annual incremental generation costs are higher in all 55 % scenarios. Main drivers are higher CO₂ costs (mid-term), and (long-term) RES & import costs which dominate diverse savings in OPEX and external effects by the end of the decade. Note: Revenues from auctioned CO₂ certificates can also be seen as a source of income.

Scenario differences: Consumer costs at EU level

Costs to consumers increase in all 55 % scenarios due to higher wholesale price levels (approx. 5 €/MWh in the 55% PM scenario), partly driven by higher CO₂ prices and net-imports. The effect is mitigated with increased availability of carbon-free renewable generation towards 2030.

Scenario differences: RES re-financing at EU level

The deployment of significant additional RES capacities increases RES system costs in the 55 % scenarios. Higher wholesale prices imply higher market revenues of RES generation and thus decrease support needs, especially in the 55 % Market based coal-to-clean scenario.

Utilization of gas capacities - EU

Full-load hours (FLH)

Comments

- In the short-term, utilization of (existing) gas capacities increases in the 55 % scenarios due to
 - CO₂ price driven fuel switch from coal to gas
 - Reduction of coal capacities
- As the expansion of replacement RES capacities increases towards 2030, the full load hours of the gas portfolio decreases to a lower level than in the 40 % scenarios
- Thus gas capacities increasingly provide capacity to the market while generation plays a decreasing role

PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

RESULTS FOR COAL-6

Total emissions & system costs – Coal-6

All coal-exit scenarios result in significant reduction of CO₂. Incremental effects of higher CO₂ prices are diminishing as coal capacity is decreasing. Additional IGC are in a similar range in the 55 % PM and 55 % MCE scenarios, while higher CO₂ price in 55 % MCTC drives IGC up significantly at EU level as it affects markets without potential for coal substitution.

Scenario differences: RES re-financing in BG

The deployment of significant additional RES capacities increases RES system costs in Bulgaria in the 55 % scenarios. Higher wholesale prices imply higher market revenues of RES generation and thus decrease support needs. The additional required RES support (compared to the 40 % PM scenario) decreases in the mid-20s before increasing slightly after 2029.

Scenario differences: Consumer costs in RO

Costs to consumers increase in all 55 % scenarios in Romania (in comparison with the 40 % PM scenario) due to higher wholesale price levels, partly driven by higher CO₂ prices and net-imports. The effect is mitigated with increased availability of carbon-free renewable generation towards 2030.

Scenario differences: RES re-financing in RO

The deployment of significant additional RES capacities increases RES system costs in Romania in the 55 % scenarios. Higher wholesale prices imply higher market revenues of RES generation and thus decrease support needs. In the case of Romania, no significant additional RES support is required, when comparing the 55 % scenarios with the 40 % PM scenario.

PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Capacity & generation – SI

Compared to the 40 % PM scenario, the 55 % scenarios lead to an earlier decommissioning & accelerated reduction of remaining coal capacities in Slovenia, which are substituted over time with a mix of wind onshore, PV & gas units (flexibility demand). The generation mix becomes less carbon-intensive & RES shares (on demand) increase by over 20 percentage points by 2030 (55 % scenarios).

PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Scenario differences: Installed capacities in SI

In the 55 % scenarios, the remaining coal capacities in Slovenia are substituted with a mix of PV, wind onshore & gas. Compared to the 55 % PM, the 55 % Market based scenarios see an earlier reduction of coal capacity (2023). Higher CO₂-prices also trigger add. market based RES expansion, especially in the 55 % Market based coal-to-clean scenario, where gas units are more strongly deployed.

Scenario differences: Power generation in SI

Earlier decommissioning and lower utilization of the remaining coal-fired units trigger temporary increased gas-based generation (mid-term) in both 55 % Market based scenarios. On the long run, coal-based generation is mostly compensated by wind and PV generation, and, in case of the 55 % Market based coal-to-clean scenario, also supplemented with significant gas-based generation by 2030.

Scenario differences: CO₂ emissions in SI

All 55 % scenarios lead to significant CO₂ savings in Slovenia compared to the 40 % PM scenario. Until 2024, the additional reduction is driven only by the CO₂ price. In total, the 55 % PM scenario results in a cumulative reduction of 23 Mio.t. of CO₂ (market based coal exit: 28 Mio.t.; market-based coal-to-clean: 35 Mio.t.) until 2030 compared to the 40 % PM scenario.

PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Scenario differences: Incremental generation costs in SI

Annual incremental generation costs in Slovenia are higher in all 55 % scenarios. Main drivers are higher import and RES costs which dominate diverse savings in OPEX and external effects by the end of the decade. Note: Revenues from auctioned CO₂ certificates can also be seen as a source of income.

METHODOLOGY & MAIN ASSUMPTIONS

Methodology & scenarios

SCENARIO DESIGN

- Definition of political scenarios
- Basis for power market modeling

ASSUMPTIONS

- Techno-economical parameters
- RES, coal trajectories
- CO₂ prices

MODELING

- Power plant dispatch & investment up to 2030
- Development of capacity and generation mix

RESULTS

- Incremental generation costs* (ICG)
- Investment volumes
- CO₂- and other emissions

MODELING APPROACH

EU-27 countries aggregated and major coal-countries as focus group („Coal-6“): BG, CZ, DE, PL, RO, SI

REGIONAL SCOPE

40 % reduction scenario

40 % Policy mix
(40 % PM)

Policy mix– “40 % Scenario” implies the former EU 2030 carbon mitigation ambition level. No significant market based coal exit or RES expansion. CO₂ price based on EC Reference 2016 sc. (35 €/t in 2030).

55 % reduction scenarios

55 % Policy mix
(55 % PM)

Policy mix - complete **coal exit until end of 2030** and increased, policy-driven RES expansion as well as elevated CO₂ prices (54 €/t in 2030 based on TYNDP2020).

55 % Market based coal exit
(55 % MCE)

Market based coal exit - coal exit trajectory resulting from relying on an economic decommissioning of all coal plants driven by the CO₂ price. RES expansion remains policy-driven.

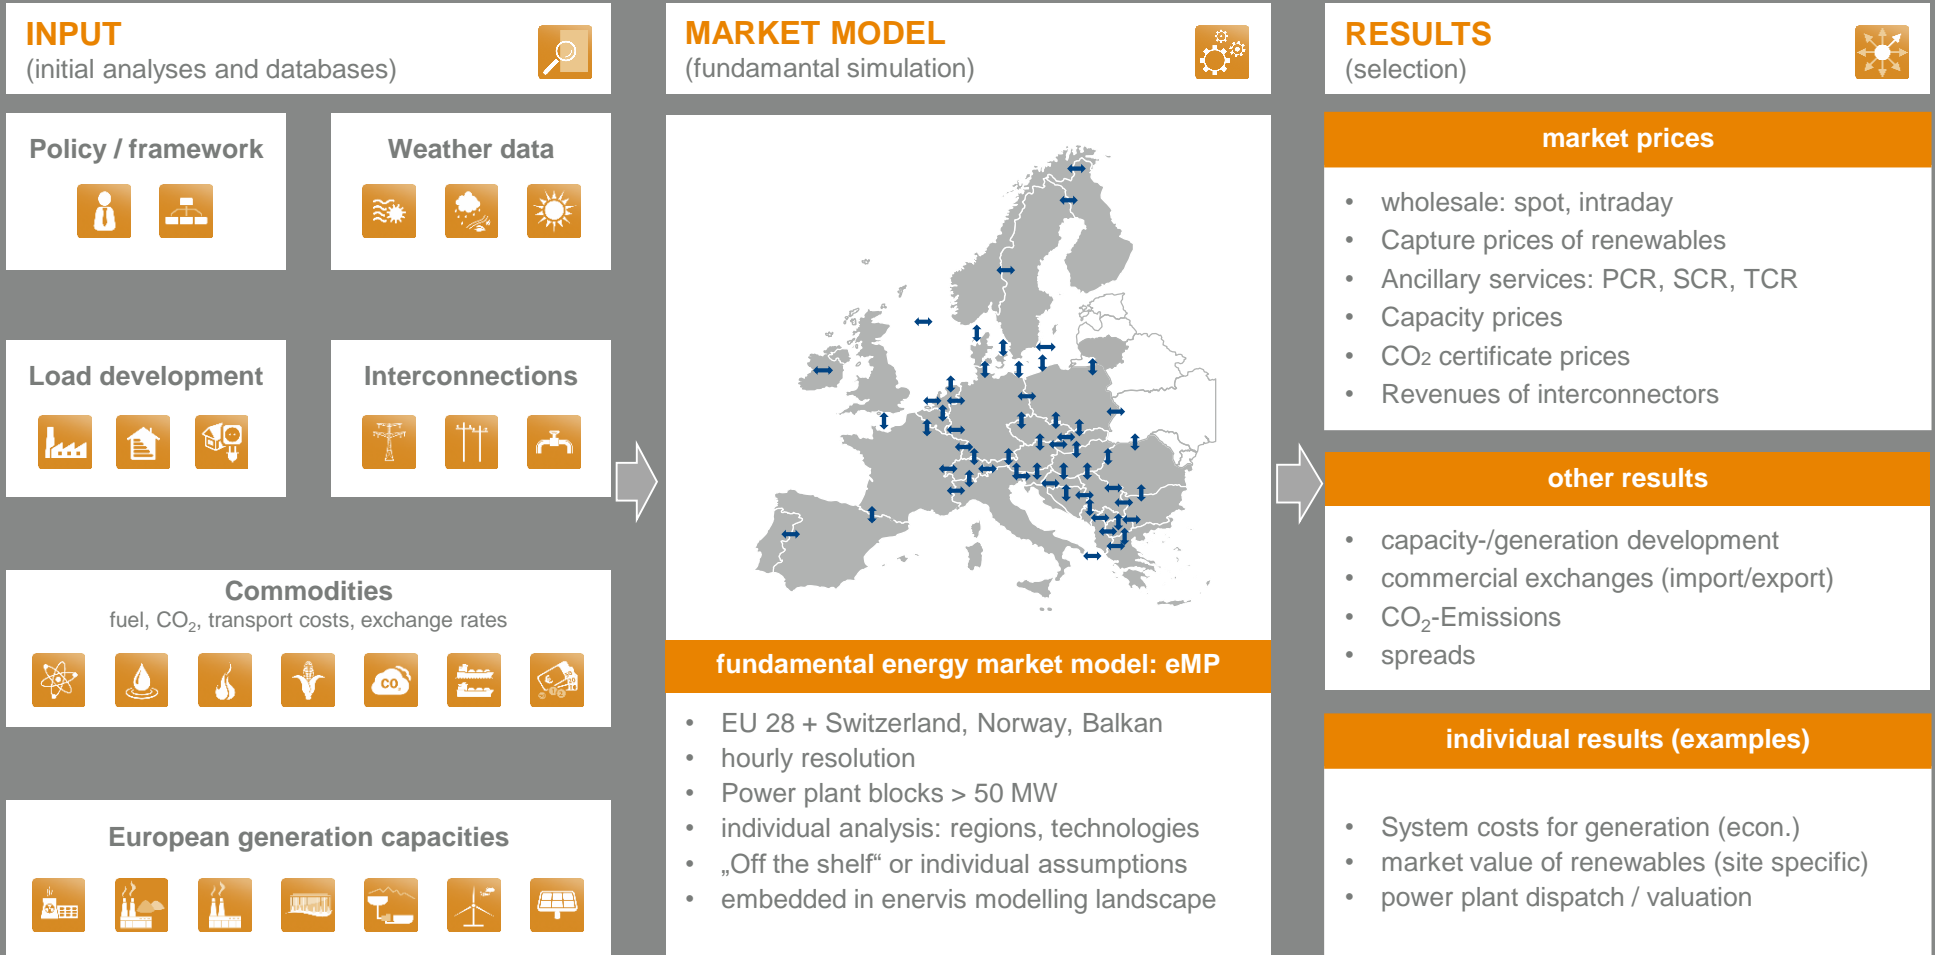

55 % market based coal-to-clean
(55 % MCTC)

Market based coal exit and RES expansion - further explores the requirements and implications of a CO₂ price-driven coal-to-clean transformation.

SCENARIOS

* For an economic comparison of scenarios the differences in generation cost are of main relevance. This study look at indicator called “Incremental generation costs”. For a detailed explanation see methodology section.

Scenario Overview (I)

Three alternatives are modelled for implementing a 2030 EU-wide coal phase-out, quantifying CO₂ prices levels corresponding to and implications of fully market-based coal phase-out and renewable phase-in versus a policy mix.

	40 % Policy mix	55 % Policy mix coal exit	55 % Market based coal exit	55 % Market based coal-to-clean
CO ₂ Prices	Ca. 35€/t in 2030 / based on EU Reference Sc. 2016	Ca. 54€/t in 2030 / based on TYNDP 2020 DE Sc.	Heuristical iteration: such that in 2030 all coal units opt for economic decommissioning (2 years of negative net margins), from 2021	Heuristical iteration: such that in 2030 renewable generation at the level of 55 % PM scenario is economically feasible
Exogenous coal trajectory	According to national plans & strategies	Phase-out of all coal capacities by 31.12.2030 (by age)	According to national plans & strategies	As resulting in 55 % MCE
Economic decommissioning of coal	none		Decommissioning according to economics but max. 2 years earlier than in 55 % PM trajectory	none
Exogenous RES trajectory	Based on NECPs	Ambitious renewable expansion to substitute coal generation (vs. 40 %)		Expansion to the same 2030 generation level as in 55 % PM scenario
Endogenous RES expansion	none	Minor additional market based expansion		

▶ Energy economic effects of a policy mix (coal phase-out, supported RES, CO₂ price increase)

▶ What level of CO₂ price can lead to a market based coal phase-out unit 2030?

▶ What level of CO₂ price can compensate RES support?

Scenario Overview (II)

Three alternatives are modelled for implementing a 2030 EU-wide coal phase-out, quantifying CO₂ prices levels corresponding to and implications of fully market-based coal phase-out and renewable phase-in versus a policy mix.

	40 % Policy mix	55 % Policy mix coal exit	55 % Market based coal exit	55 % Market based coal-to-clean
Fuel Prices	Based on WEO 2020 projections			
Gas Capacities	Merchant driven deployment in all regions / partial CHP replacement			
Nuclear Capacities	Existing: According to exit plans or lifetime assumption where applicable / Newly built units not relevant until 2030 or realization not assumed in EU countries			
Demand	According to national projections and sources / NECPs / partial electrification of mobility and heating sectors based on enervis assumptions			
Security of Supply	Peak Load, availability... etc. according to selected sources			
DSM	DSM potential assumed to be 5 % of national peak load			
Interconnection	Based on entso-e data and TYNDP Projects			

Fuel & CO₂ price* assumptions

Fuel prices are the same across all four scenarios. CO₂ prices are differentiated depending on scenario-specific reduction ambition and implied policy approach.

Coal price

- In all scenarios, 2030 figures are based on WEO 2020 Stated Policies Scenario
- 2020 figure based on historical data
- 2021 figure based on future quotes Jan/Feb 2021

Gas price

- In all scenarios 2030 figures are based on WEO 2020 Stated Policies Scenario
- 2020 figure based on historical data
- 2021 figure based on future quotes Jan/Feb 2021

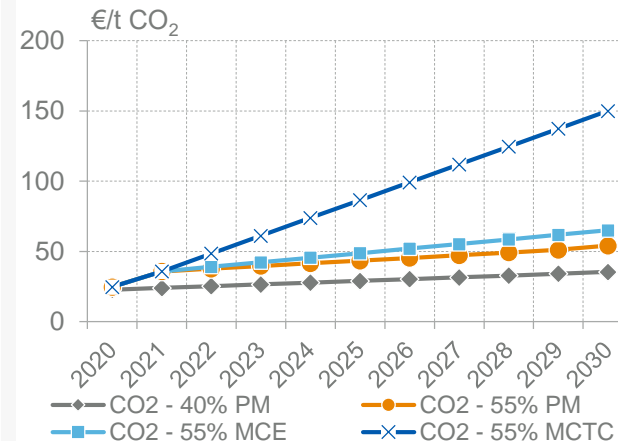

Oil price

- In all scenarios, 2030 figures are based on WEO 2020 Stated Policies Scenario
- 2020 figure based on historical data
- 2021 figure based on future quotes Jan/Feb 2021

CO₂ price (EU ETS)

- 55 % PM 2030 level based on TYNDP 2020 Distributed Energy Sc.
- 40 % PM 2030 level based on EC Ref. 2016
- 2021 figure based on future quotes Jan/Feb 2021

* all figures real (base 2021)

Incremental generation costs (I)

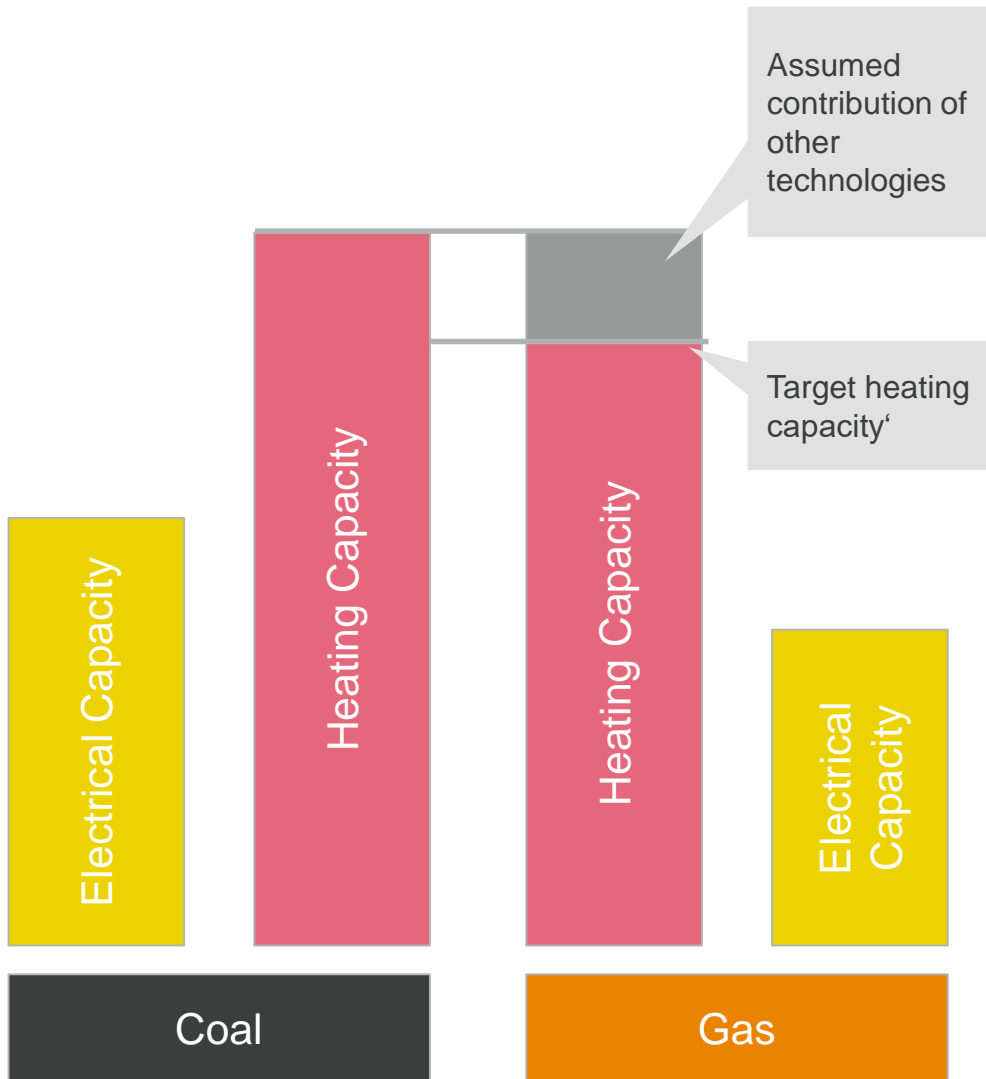

- For an economic comparison of scenarios the differences in generation cost are of main relevance. This study look at indicator called “Incremental generation costs”.
- **Generation costs** are costs that are caused when generating (or importing) power in a country or system. These costs typically include all variable and fixed costs (including costs of capital) for building and operating power generation units.
- **Incremental** generation costs includes costs that change in between scenarios, whereas all costs that occur in all scenario do not influence “merit” in comparison and are this not necessarily included.
- If generation costs are comparatively lower in one scenario vs. another, this means that power is generated more cost efficiently, which can either reduce end-consumer costs or increase rents (“profits”) of power producers by the same amount (or, of course, both partially). Since both producer rents and consumer prices are, from an economic point of view, distributional in nature, economic efficiency is often assessed based on generation costs.

Incremental generation costs (II)

In this project we have defined the following cost elements:

- **Net-Import Costs:** Any increase in net-power import from surrounding market zones has to be taken into consideration and was therefore assessed based on wholesale import prices.
- **External Effects:** External effects (mostly) represent negative health effects caused by pollutants emitted in the context of coal-based power generation, for the sake of comparability, these negative health effects were evaluated in monetary terms and expressed as costs.
- **CO₂ Costs:** This includes all costs caused by procurement of CO₂ certificates within the ETS. Please note, that these costs also create additional income e.g. for governmental institutions.
- **OPEX:** This component covers operational costs of conventional power generation. This includes fuel costs but, in this instance excludes carbon costs, which were addressed separately.
- **CAPEX:** Capital costs caused by conventional power generation. This represents investment and capital costs.
- **RES Costs:** All costs relevant for investing in and operation of renewable energy sources (OPEX and CAPEX of RES).

Assumptions for replacing coal-based CHP plants

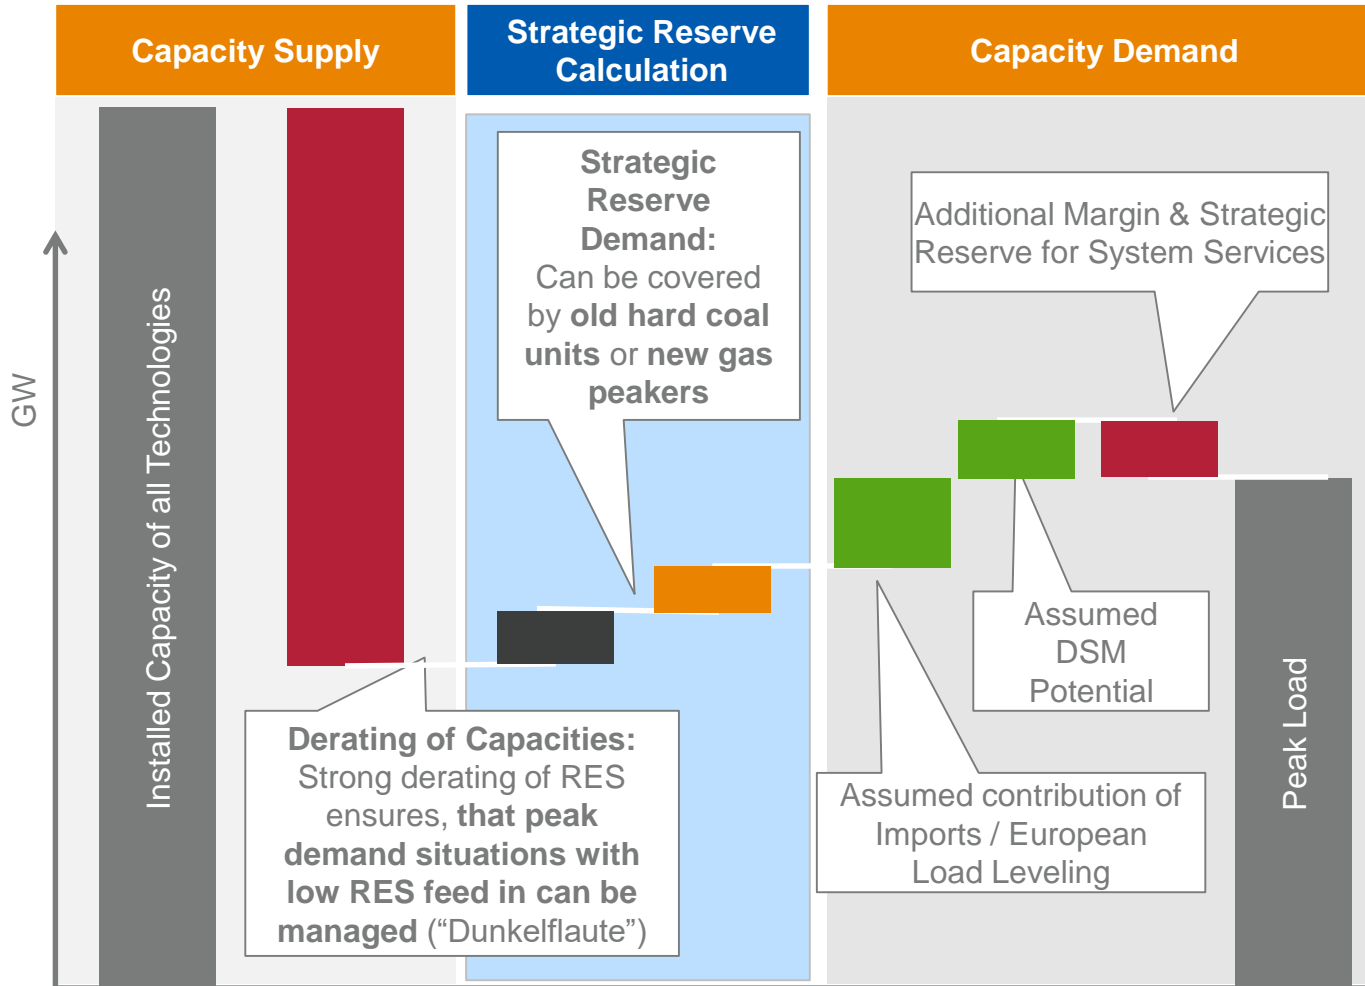

Comments

- In this project a simplified 'heat capacity balancing approach' was conducted.
 1. Based on Eurostat data and typical technology parameters of coal CHP plants, heating capacity of coal plants was estimated.
 2. Heating capacity was reduced by a country specific factor representing an assumed contribution of other technologies (e.g. RES heating)
 3. This 'Target heating capacity' was substituted by heating capacity of gas plants
 4. Based on typical technology parameters of CHP gas plants, electrical capacity of gas plants was calculated.
 5. Actual heat generation to be optimized by the power market model

STRATEGIC RESERVES

Assumptions for deriving strategic reserve capacities

In this project, a “Capacity Balancing Approach” was used to calculate strategic reserve demand on a national level / If these strategic reserves are contracted, even so called “Dunkelflaute” situations should be manageable.

- Calculations are based on the assumption, that hard coal units can contribute to the strategic reserve for up to 10 years after market exit.
- Additional assumptions:
 - Required Margin on peak load = 9 %
 - DSM can reduce peak load by 5 %
 - European levelling effects can reduce peak load (pro rata) by 7.5 %
 - Capacity credit of RES: PV = 0 %; onshore = 4 %, offshore = 7 %

Strategic reserve deltas – Coal-6

In comparison with the 40 % PM scenario, the 55 % scenarios see additional strategic reserve needs* in the Coal-6 countries from the mid-2020s onwards. In the 55 % Market based coal-to-clean scenario, this trend changes, and by the end of the decade (2028 onwards) lower strategic reserve capacities are required due to additional gas & (partially) wind onshore in the power systems.

55 % PM

Strategic reserve Cum. invest cost of strategic reserve

55 % MCE

Strategic reserve Cum. invest cost of strategic reserve

55 % MCTC

Strategic reserve Cum. invest cost of strategic reserve

Note: No net demand for newly built strategic reserves is caused if hard coal units decommissioned in the 55% scenarios can be utilized as reserves. Hence costs depicted in this slide represent the costs of reserves if the capacity had to be provided by newly built gas units (OCGT) and hence would be lower in case decommissioned coal would be used instead.

Note: Graphs depict scenario differences to the 40% PM scenario (e.g. 55 % PM minus 40 % PM). PM = Policy mix; MCE = Market-based coal-exit; MCTC = market-based coal-to-clean

Strategic reserve deltas – BG

The capacity balancing approach leads to additional strategic reserve requirements for Bulgaria beyond those the power market model would deploy based on market price signals alone. 2026 onwards, additional capacities would be required in all 55 % scenarios for ensuring peak load to be served primarily on a national basis.

55 % PM

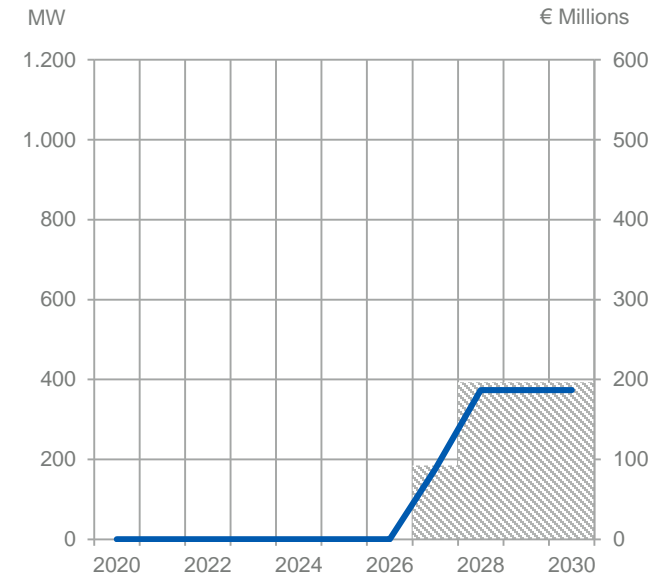

Strategic reserve Cum. invest cost of strategic reserve

55 % MCE

Strategic reserve Cum. invest cost of strategic reserve

55 % MCTC
